UNITS 4 & 5

PROPOSITIONAL LOGIC, BOOLEAN ALGEBRA AND CIRCUIT DESIGN & HARDWARE AND COMPUTER ARCHITECTURES

STUDY GOALS

0

- Understand the basic language and concepts of propositional logic.
- Learn how to create truth tables.
- Find out how to use the conjunctive and disjunctive normal form.
- Learn about the basic concepts of digital circuits and logic gates.

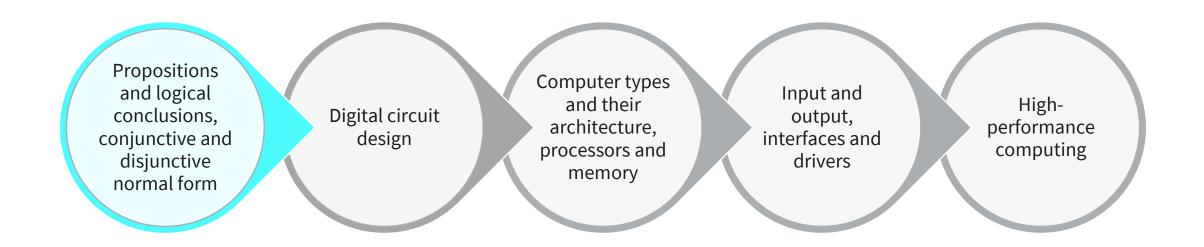

STUDY GOALS

- Learn the basic elements of computer architecture.
- Understand how processors and memory work.
- Explore how a computer processes input and output.
- Learn how operating systems and hardware communicate.
- Get an overview of high-performance computing.

- 1. What is a register?
- 2. What is the difference between a data bus and an address bus?
- 3. What is a computer cluster?

PROPOSITIONAL LOGIC, BOOLEAN ALGEBRA AND CIRCUIT DESIGN

PROPOSITIONAL LOGIC (PL)

- logical constants: true, false
- propositional symbols: P, Q, S, ... (atomic sentences)
- wrapping parentheses: (...)
- literal: atomic sentence or negated atomic sentence
- sentences are combined by **connectives**:

Connectives	Туре	Example
∧and	[conjunction]	action or instance of two or more events or things occurring at the same point in time or space "a conjunction of favorable political and economic circumstances"
∨or	[disjunction]	A disjunction is a compound statement formed by joining two statements with the connector OR.
		"a disjunction by either favorable political or economic circumstances"
⇒implies	[implication / conditional]	
⇔…is equivalent	[biconditional]	
¬…not	[negation]	

EXAMPLES OF PL SENTENCES

 $(P \land Q) \rightarrow R$ - "If it is hot and humid, then it is raining." $Q \rightarrow P$ - "If it is humid, then it is hot." - "It is humid." – Ho = "It is hot." A better way: - Hu = "It is humid." – R = "It is raining."

PROPOSITIONAL LOGIC

- a simple language useful for showing key ideas and definitions
- User defines a set of propositional symbols, like P and Q.
- User defines the **semantics** of each propositional symbol:
 - Ho means "It is hot"
 - Hu means "It is humid"
 - R means "It is raining"

A sentence (well-formed formula) is defined as follows:

- A symbol **S** is a sentence.
- If **S** is a sentence, then \neg **S** is a sentence.
- If S is a sentence, then (S) is a sentence.
- If **S** and **T** are sentences, then $S \vee T$, $S \wedge T$, $S \rightarrow T$, and $S \leftrightarrow T$ are sentences.
- A sentence results from a finite number of applications of the above rules.

The definition of conjunctive normal form is a logic formula that is a single conjunction of any number of disjunctions.

$$p \lor \neg q \land r \lor s$$

There can be any number of disjunctions as long as they are joined by a conjunction.

To evaluate the results of the logic formula above, we can create a truth table.

The other normal form, disjunctive, is one where any number of conjunctions are connected by a disjunction. In other words, something like this:

$$p \wedge q \vee \neg r \wedge \neg s$$

This could be read as "p and q or not r and not s."

This is two conjunctions connected by a disjunction, and the parentheses tell us which to evaluate first.

TRUTH TABLES

р	q	(p∧q) and
F	F	F
F	Т	F
Т	F	F
Т	Т	Т

р	q	(p∨q) or
F	F	F
F	Т	Т
Т	F	Т
Т	Т	Т

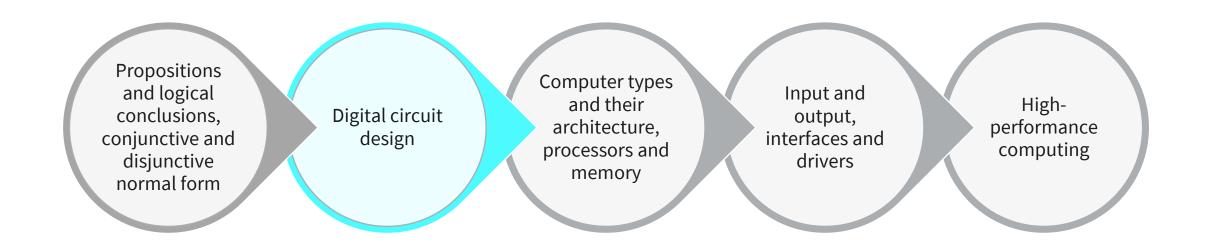

р	q	(p → q) If then
F	F	Т
F	Т	Т
Т	F	F
Т	Т	Т

р	¬p not
F	Т
Т	F

PROPOSITIONAL LOGIC, BOOLEAN ALGEBRA AND CIRCUIT DESIGN

BOOLEAN OPERATORS

Logical AND

a AND *b* is 1, if *a*=1 and *b*=1

Logical OR

a OR *b* is 1, if *a*=1 and/or *b*=1

Exklusive OR (XOR)

 $a \times A \times B$ is 1, if either a=1 or b=1

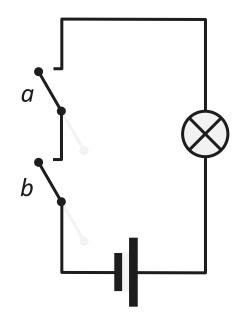

Logical NOT

NOT a (NOT b) inverts the argument

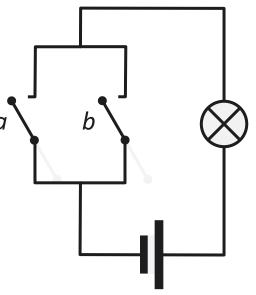

а	b	AND	OR	XOR	NAND	NOR	NXOR*	a/b	NOT
0	0	0	0	0	1	1	1	0	1
0	1	0	1	1	1	0	0	1	0
1	0	0	1	1	1	0	0		
1	1	1	1	0	0	0	1	*also: X	NOR

BOOLEAN ALGEBRA

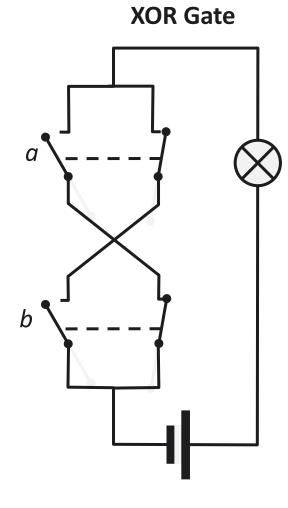

AND Gate

а	b	AND	OR	XOR	
0	0	0	0	0	-
1	0	0	1	1	
0	1	0	1	1	
1	1	1	1	0	

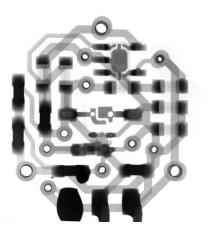

LOGIC GATES

We have looked at Boolean functions in abstract terms.

 In this section, we see that Boolean functions are implemented in digital computer circuits called gates.

A gate is an electronic device that produces a result based on two or more input values.

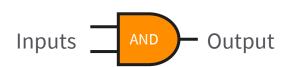

- In reality, gates consist of one to six transistors, but digital designers think of them as a single unit.
- Integrated circuits contain collections of gates suited for a particular purpose.

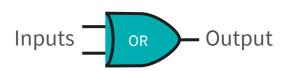

GATES

A pictorial representation of AND, OR, XOR, and NOT gates as well as their input and output values

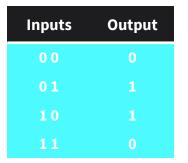

Inputs	Output
0 0	0
0 1	0
10	0
11	1

Inputs	Output
0 0	0
0 1	
10	
11	

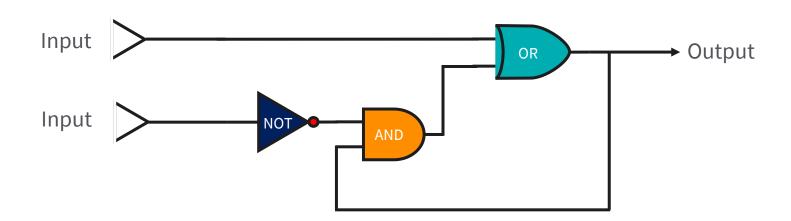

Inputs	Output
0 0	1
01	0

FLIP-FLOPS

Circuits built from gates that act as a fundamental unit of computer memory

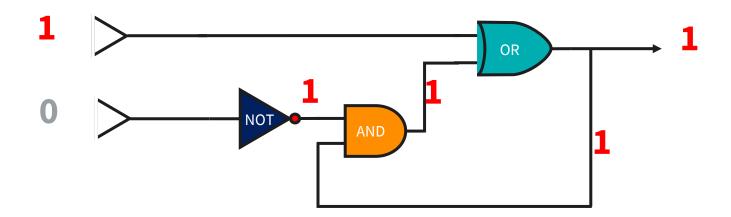

- One input line is used to set its stored value to 1.
- One input line is used to set its stored value to 0.
- While both input lines are 0, the most recently stored value is preserved.

A simple flip-flop circuit

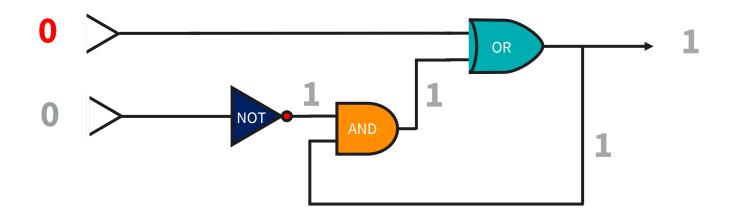

SETTING THE OUTPUT OF A FLIP-FLOP TO 1

- a. First, a 1 is placed in the upper input.
- b. This causes the output of the OR gate to be 1 and the output of the AND gate to be 1.

SETTING THE OUTPUT OF A FLIP-FLOP TO 1

- a. First, a 1 is placed in the upper input.
- b. This causes the output of the OR gate to be 1 and the output of the AND gate to be 1.
- c. Finally, the 1 from the AND gate keeps theOR gate from changing after the upper input returns to 0.

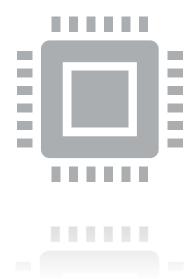

DESIGNING CIRCUITS

We have seen digital circuits from two points of view: digital analysis and digital synthesis.

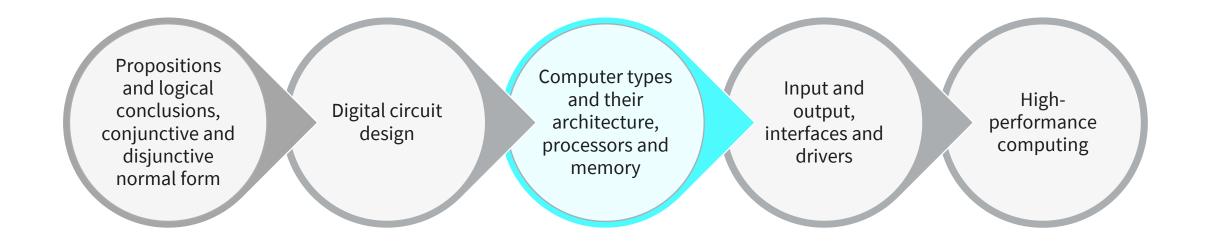

- Digital analysis explores the relationship between a circuit's inputs and its outputs.
- Digital synthesis creates logic diagrams using the values specified in a truth table.

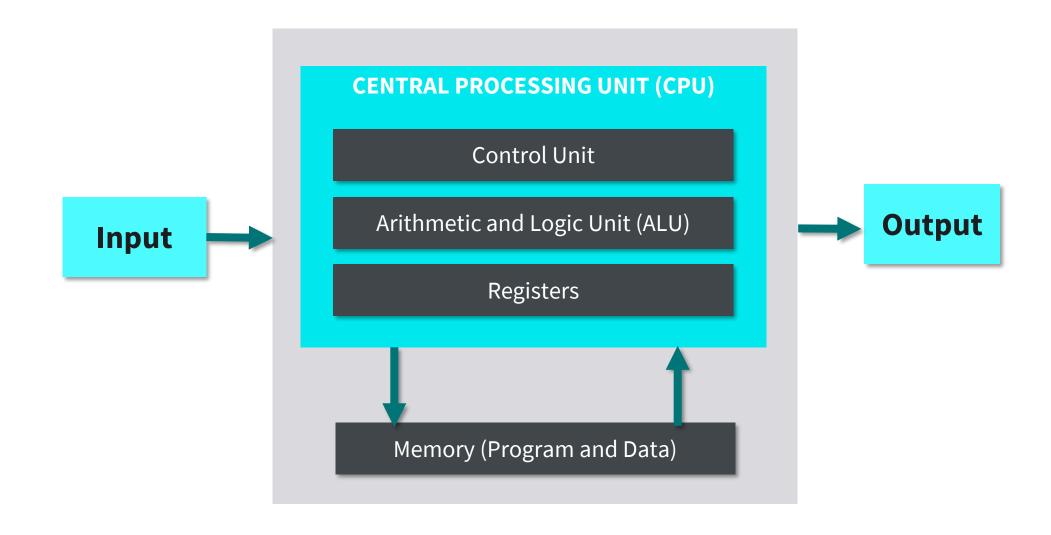

Software is a collection of algorithms that could just as well be implemented in hardware.

Principle of Equivalence of Hardware and Software.

PROPOSITIONAL LOGIC, BOOLEAN ALGEBRA AND CIRCUIT DESIGN

CONTROL AND STATUS REGISTERS

Four registers are essential to instruction execution:

Program counter (PC)

contains the address of an instruction to be fetched

Instruction register (IR)

contains the instruction most recently fetched

Memory address register (MAR)

contains the address of a location in memory

Memory buffer register (MBR)

contains a word of data to be written to memory or the word most recently read

COMPUTER BUS

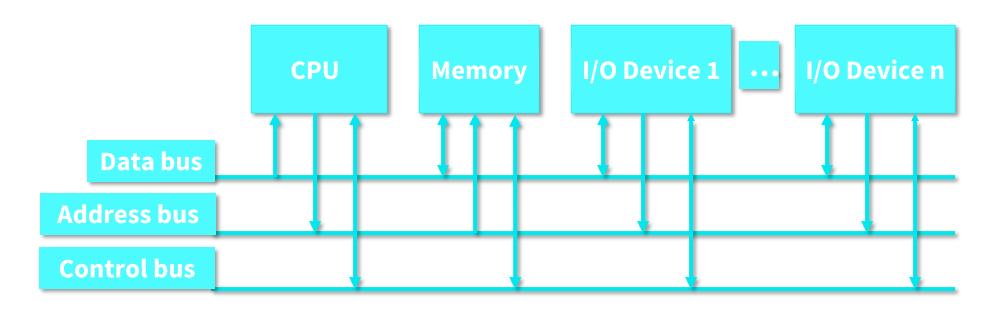

A **bus** is a set of parallel conductors **that transfer data** between different components of a computer.

A bus has three main parts:

- Data bus
 - carries data
- Address bus
 - carries the address of data
- Control bus
 - carries control signals

BUS-ORIENTED COMPUTER ARCHITECTURE

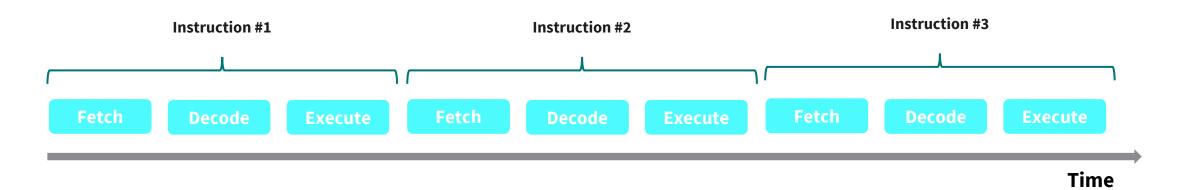

INSTRUCTION CYCLE

The control unit in all Central Processing Units (CPUs) follows the same basic instruction processing sequence:

- 1. Fetch the instruction.
- 2. Decode the instruction.
- 3. Execute the instruction.

On traditional CPUs, these phases are typically executed sequentially as shown:

MEMORY TERMINOLOGY

Random Access Memory (RAM): Memory in which individual cells can be easily accessed in any order

Dynamic Memory (DRAM): RAM composed of volatile memory

MEASURING MEMORY CAPACITY

Kilobyte = 1024 bytes

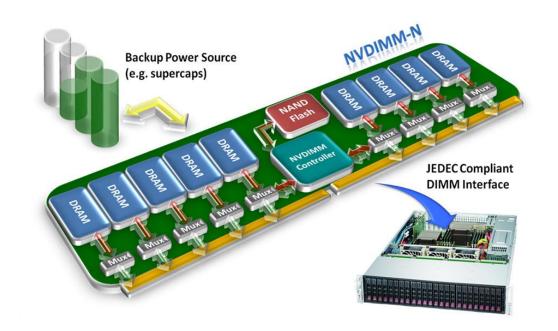

Example: 3 KB = 3 times 1024 bytes

Megabyte = 1,048,576 bytes

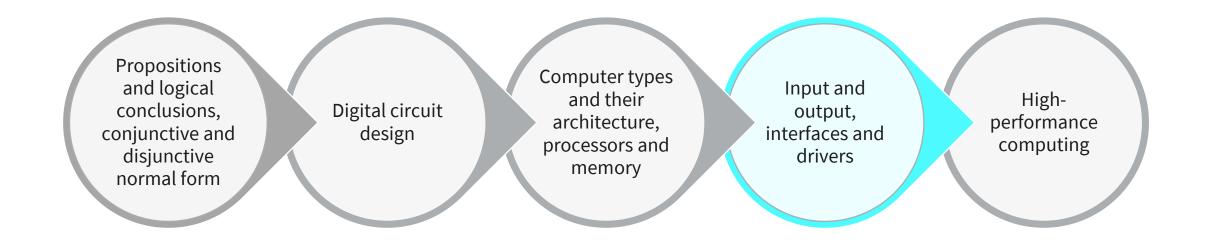

Example: 3 MB = 3 times 1,048,576 bytes

Gigabyte = 1,073,741,824 bytes

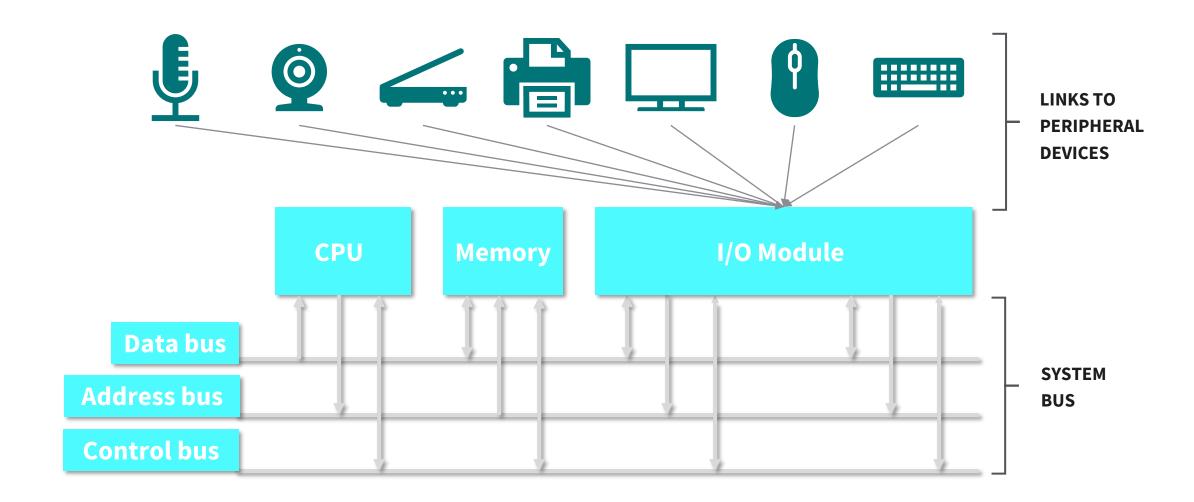

Example: 3 GB = 3 times 1,073,741,824 bytes

HARDWARE AND COMPUTER ARCHITECTURES

GENERIC MODEL OF AN I/O MODULE

EXTERNAL DEVICES

- Provide a means of exchanging data between the external environment and the computer
- Attach to the computer by a link to an I/O module
 - The link is used to exchange control, status, and data between the I/O module and the external device
- Peripheral device
 - An external device connected to an I/O module

Three categories:

Human readable

- suitable for communicating with the computer user
- video display terminals (VDTs), printers

Machine readable

- suitable for communicating with equipment
- magnetic disk and tape systems, sensors and actuators

Communication

- suitable for communicating with remote devices such as a terminal, a machine-readable device, or another computer

The major functions for an I/O module fall into the following categories:

Control and Processor Device Data buffering Error detection communication timing communication performs the detects and coordinates involves involves needed reports the flow of command commands, transmission buffering traffic between decoding, data, status operation to errors internal information, status balance device reporting, and data resources and and memory external address speeds devices recognition

THREE TECHNIQUES ARE POSSIBLE FOR I/O OPERATIONS

Three techniques are possible for I/O operations:

Programmed I/O

- Data is exchanged between processor and the I/O module.
- Processor executes a program that gives it direct control of the I/O operation.
- When the processor issues a command, it must wait until the I/O operation is complete.
- If the processor is faster than the I/O module, it wastes processor time.

Interrupt-driven I/O

 Processor issues an I/O command, continues to execute other instructions, and is interrupted by the I/O module when the latter has completed its work.

Direct memory access (DMA)

The I/O module and main memory exchange data directly without processor involvement.

DEVICE DRIVER AND OPERATING SYSTEM

What do you with a device?

- {read, write}
- {read only}
- {write only}

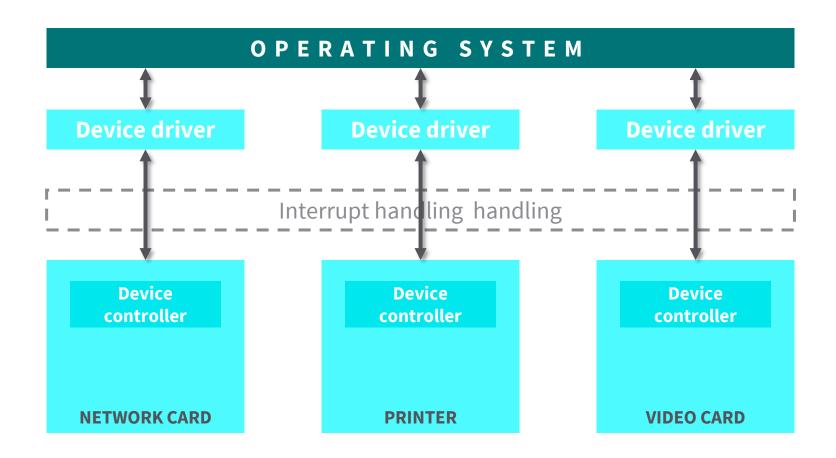

Let's look at some examples:

- USB device
- CD-ROM
- LED Display
- ...

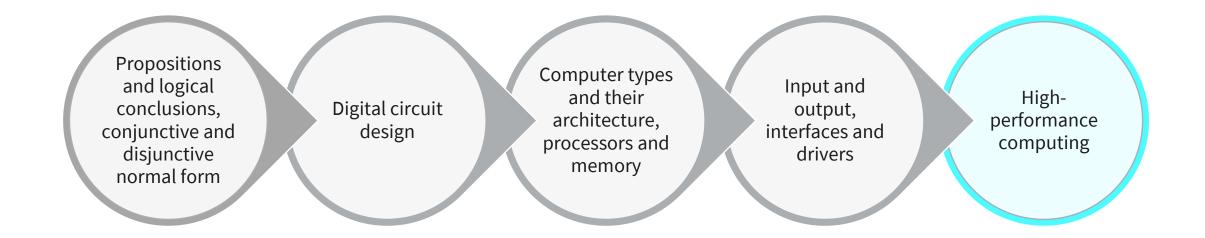

What do you do with a file?

open, close, read, write, ...

File is an excellent abstraction for devices.

HARDWARE AND COMPUTER ARCHITECTURES

SUPERCOMPUTER

Supercomputers are designed for high calculation performance and are used in simulation, product development, and research to solve **Grand Challenges**.

Performance is measured in floating point operations per second (FLOPS).

Grand Challenges are fundamental complex problems from engineering and natural sciences.

Examples are:

- quantum states for quantum computing
- properties of matter for quantum chromodynamics
- electronic structures of catalysts and semiconductors
- plasma dynamics in fusion reactors
- combustion dynamics
- fluid raw material dynamics
- weather dynamics

Computer performance				
Name	Unit	Value		
<u>kilo</u> FLOPS	kFLOPS	10 ³		
<u>mega</u> FLOPS	MFLOPS	10 ⁶		
gigaFLOPS	GFLOPS	109		
<u>tera</u> FLOPS	TFLOPS	10 ¹²		
<u>peta</u> FLOPS	PFLOPS	10 ¹⁵		
<u>exa</u> FLOPS	EFLOPS	10 ¹⁸		
<u>zetta</u> FLOPS	ZFLOPS	10 ²¹		
<u>yotta</u> FLOPS	YFLOPS	10 ²⁴		

CLUSTER AND GRID

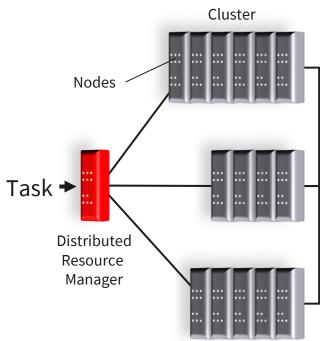

Computer cluster: High-performance computers typically consist of multiple homogeneous computers in parallel processing with centralized administration.

Grid-Computing uses multiple loosely coupled clusters to create a virtual high-performance computer. While a grid is usually not managed centralized, it requires a **Distributed Resource**Manager to distribute the tasks.

Typical fields of application are

- scientific calculations (e.g., CERN, SETI).
- simulation (e.g., drag coefficients).
- product innovation/development.

Service Grids are conceptual predecessors of Cloud Computing.

REVIEW STUDY GOALS

- Understand the basic language and concepts of propositional logic.
- Learn how to create truth tables.
- Find out how to use the conjunctive and disjunctive normal form.
- Learn about the basic concepts of digital circuits and logic gates.

REVIEW STUDY GOALS

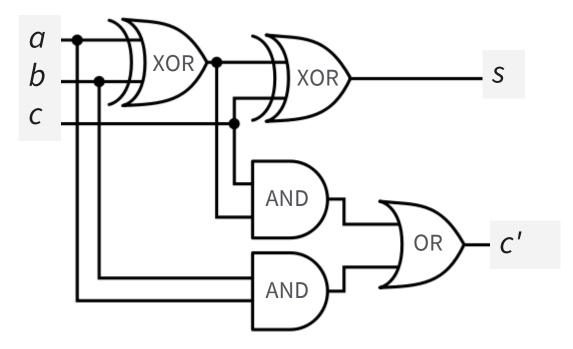

- Learn the basic elements of computer architecture.
- Understand how processors and memory work.
- Explore how a computer processes input and output.
- Learn how operating systems and hardware communicate.
- Get an overview of high-performance computing.

SESSION 3

TRANSFER TASK

The following is a combination of logical operators as electronic circuits.

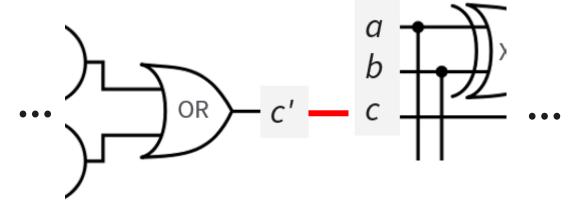

TRUTH TABLE

а	b	С	S	c'
0	0	0		
0	1	0		
1	0	0		
1	1	0		
	0	0 0 0 1	0 0 0 0 1 0 1 0 0	0 0 0 0 1 0 1 0 0

а	b	С	S	c'
0	0	1		
0	1	1		
1	0	1		
1	1	1		

- ${f 1.}\;$ Complete the truth table next to the circuit.
- 2. What is the circuit doing?
- 3. Combine 4 of these circuits by connecting **c**' with **c**:

- 4. What is the combined circuit doing then?
- 5. How are multiplications e.g., 12x17 performed using such a simple circuit?

TRANSFER TASK PRESENTATION OF THE RESULTS

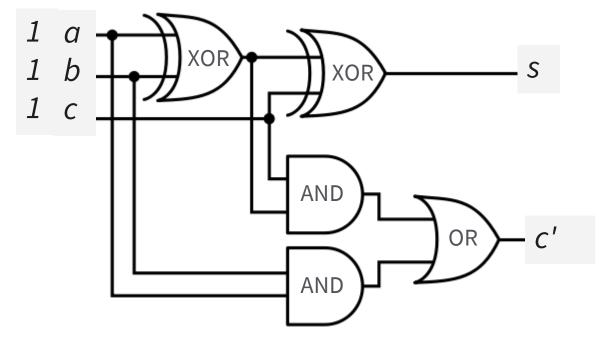

Please present your results.

The results will be discussed in plenary.

The circuit is called a 1-bit full adder. He is adding bits. c' is the carry bit.

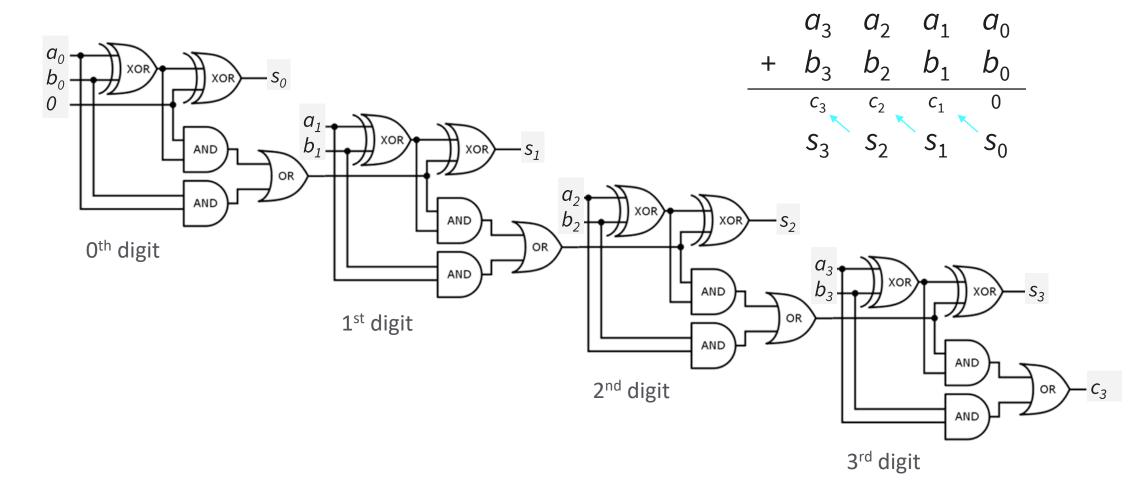

TRUTH TABLE

а	b	C		
0	0	0	0	0
0	1	0	1	0
1	0	0	1	0
1	1	0	0 1 1 0	1

а	b	C		
0	0	1	1 0 0	0
0	1	1	0	1
1	0	1	0	1
1	1	1	1	1

Combination of multiple full adders – here 4 – creates a 4-bit full adder. We can add 4 bits.

SAMPLE SOLUTION: 5 CALCULATIONS OVER ADDITIONS

Computers are actually only capable of addition and logical bit shifts. All calculations are realized via these

two operations:

An example of a multiplication: the number 12 is to be multiplied by 17. The factor for the multiplication (17) is decomposed into the next smaller power of two. In our example this would be $16 = 2^4$. The exponent (e=4) and the remainder (R=1) are stored temporarily. Now the multiplication 12×16 can just be done by 4 (e) shift operations of the operand. For this all bits are shifted by one to the left (logical left shift, LSL). Each shift operation doubles the value of the number. Then the operand is added R times to the result; in our case only once. The result is 204.

	Binary	Decimal	Operation
	00001100	12	Operand (a)
	00010001	17	Faktor (b)
1	00011000	24	LSL a (x2)
2	00110000	48	LSL a (x4)
3	01100000	96	LSL a (x8)
4	11000000	192	LSL a (x16)
5	11001100	204	ADD a (+12)

More complex calculations can ultimately be realized via additive series, such as the root (infinite series) or the natural logarithm (Taylor series). All other operations are also carried out simply via an enormous number of addition and shift operations, whether it is a data management system or a computer game. So digital computers are actually quite stupid, but extremely fast.

- 1. If you wanted to make sure that p and q both were true, you would use which connector?
 - a) disjunction
 - b) conjunction
 - c) negation
 - d) implication

- 2. To list all possible outputs for logic inputs, you would create what kind of table?
 - a) logic
 - b) data
 - c) truth
 - d) circuit

LEARNING CONTROL

3. An XOR gate means that the inputs:

- a) are the same
- b) are different
- c) are both "1"
- d) are both "0"

LEARNING CONTROL

- 4. A supercomputer uses what kind of processing?
 - a) serial
 - b) intermittent
 - c) parallel
 - d) NAND

- 5. What does an operating system provide to interact with the user?
 - a) interface
 - b) CPU
 - c) motherboard
 - d) device driver
